

Computer Organization & Architecture (KCS-302)

Unit -1 :- Introduction : Functional units of digital system & their interconnections, buses, bus architecture. Types of buses and bus arbitration, Register, bus & memory transfer, Process organization, general Register organization, stack organization and addressing modes.

computer organization & Architecture

Architecture + Organization

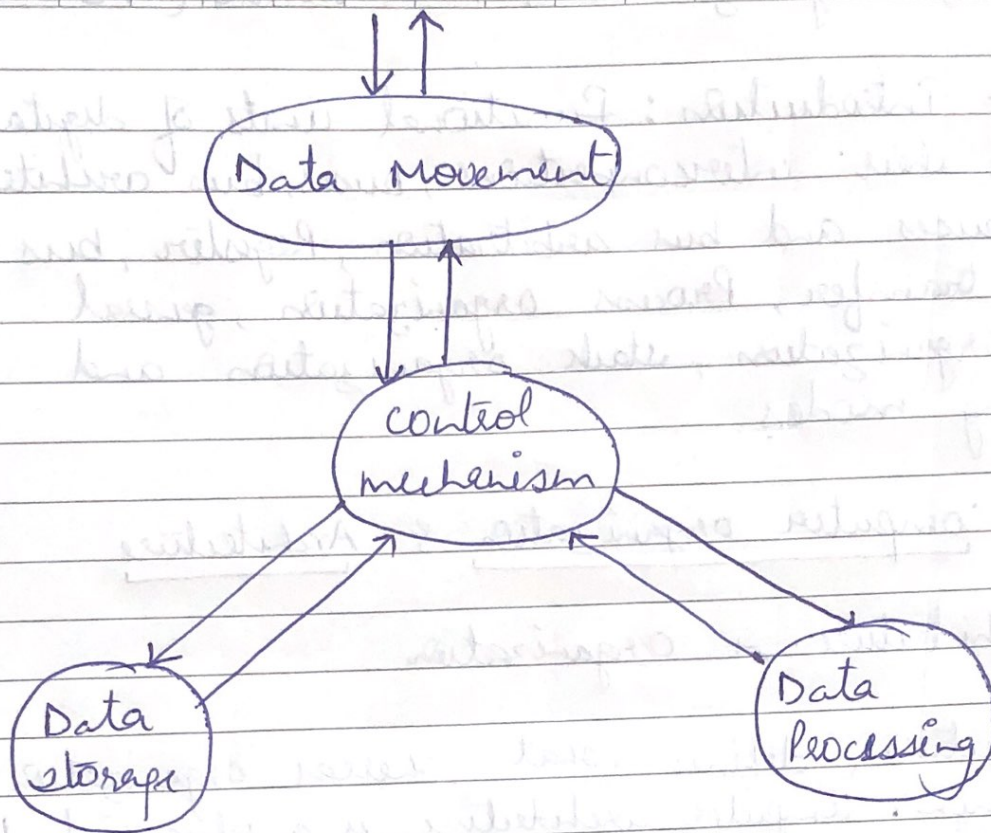

- Architecture defines what whereas organization defines how. Computer architecture is a blueprint for design & implementation of computer. Computer organization is how operational parts of a computer system are linked.

Basic functioning of computer :-

functions of computer :-

- ① Data Processing
- ② Data storage
- ③ Data movement
- ④ control - control controls above three functions

structural components:- There are 4 main structural components:-

- CPU
- Main Memory
- I/O
- system interconnections

- CPU structural components:
 - control unit
 - Arithmetic & logic unit
 - Registers
 - CPU interconnections

Computer Architecture

① describes what the computer does

② CA deals with functional behaviour of computer system.

③ It deals with high level design issues

④ Architecture indicates its hardware

⑤ Also called instruction set architecture

⑥ comprises logical functions such as instruction sets, registers, data types and addressing modes

⑦ coordinates b/w the hardware & s/w of the system

- eg intel x86 same basic architecture 8086, 80186, 80286

- IBM system/370 share same basic structure

- code compatibility exists backwards

- Pentium & x86 share same architecture b/w different organization.

Computer ^{Date} Organization

describes how it does it

CO deals with structural relationship.

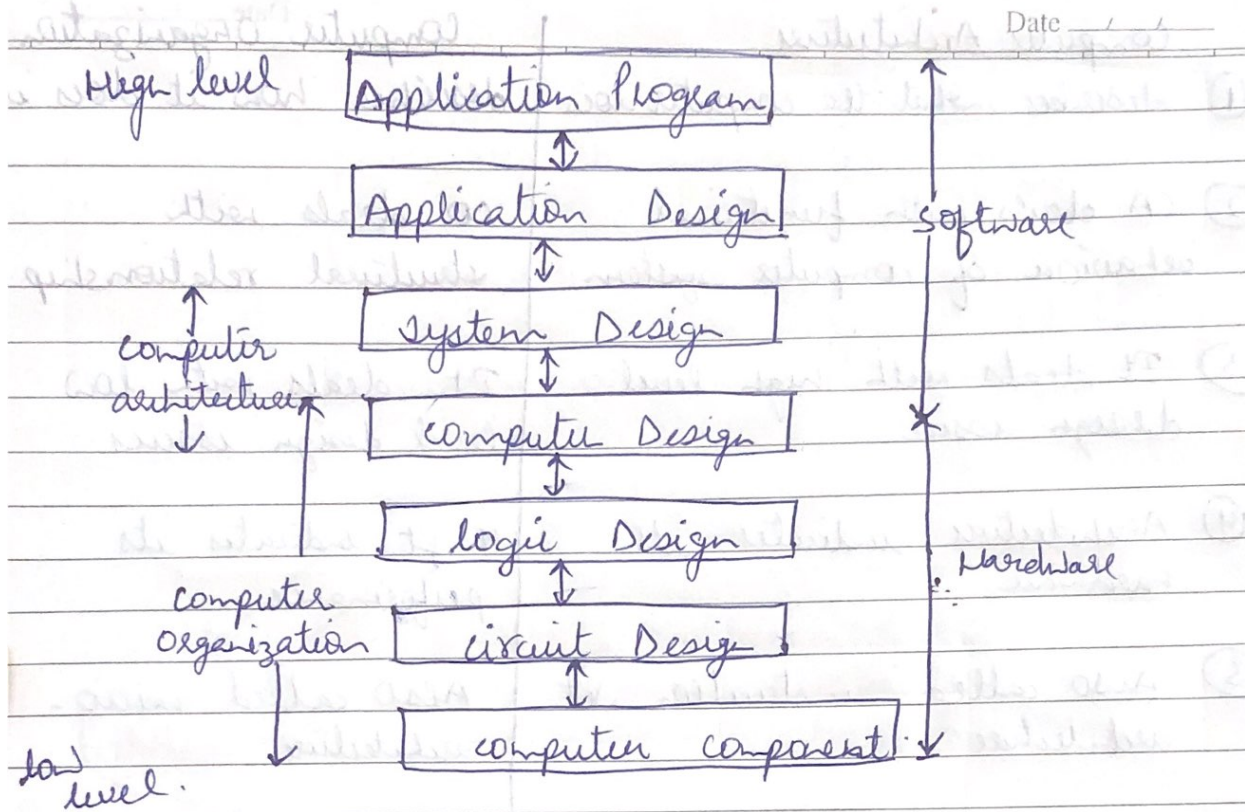

It deals with low level design issues

It indicates its performance

Also called micro-architecture

consists of physical units like circuit design, peripheral & address

handles the segments of n/w in a system.

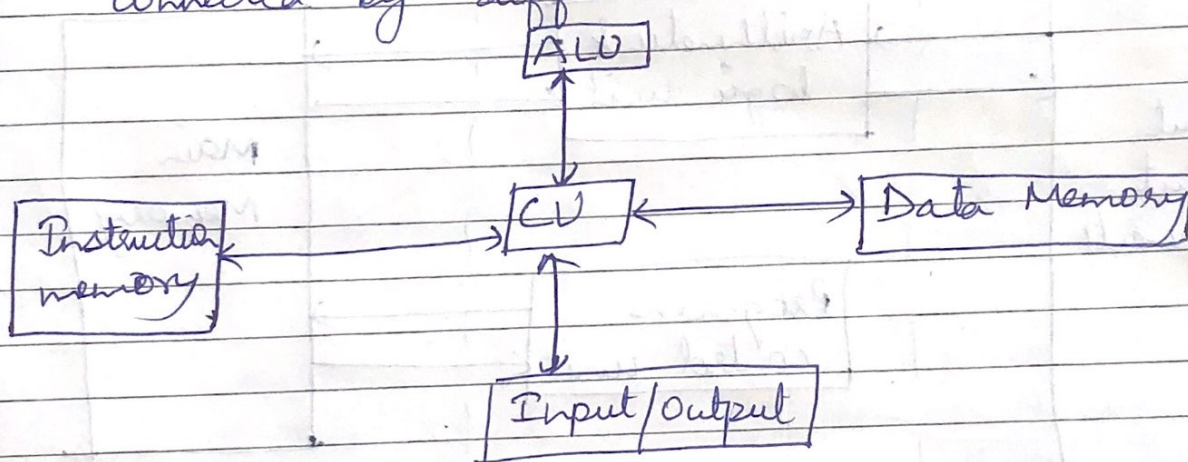

Two basic type of computer architectures:-

- stored program concept was introduced.
- Von neumann architecture
- Harvard architecture

Von-neumann architecture is also known as Princeton architecture. In von-neumann architecture, a memory is used to store instructions & data. The bottleneck of von-neumann architecture is instruction fetch and a data operation cannot occur at the same time because they share a common bus.

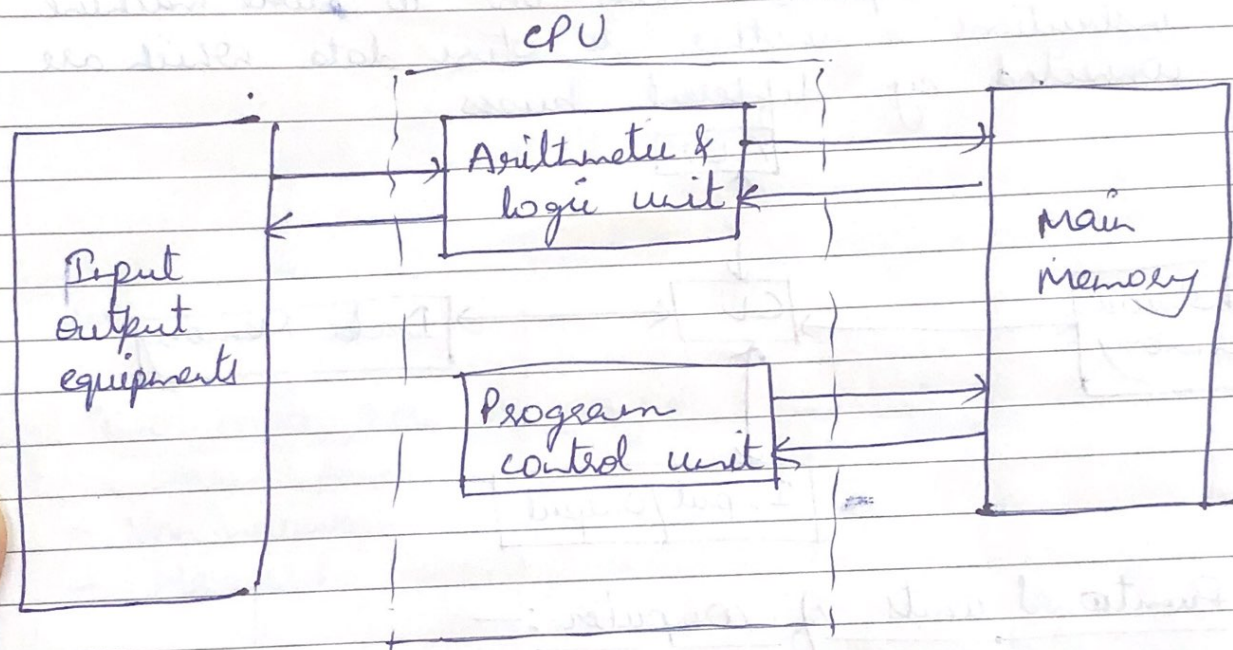

Harvard architecture:- early computer system, machine instructions were stored on punch cards & data could be stored on another media such as magnetic tape. This kept the instructions & data entirely separate from one another, known as Harvard architecture. In modern computer, this approach can be achieved by using a CPU with two separate units one to store machine instructions & another to store data which are connected by different buses.

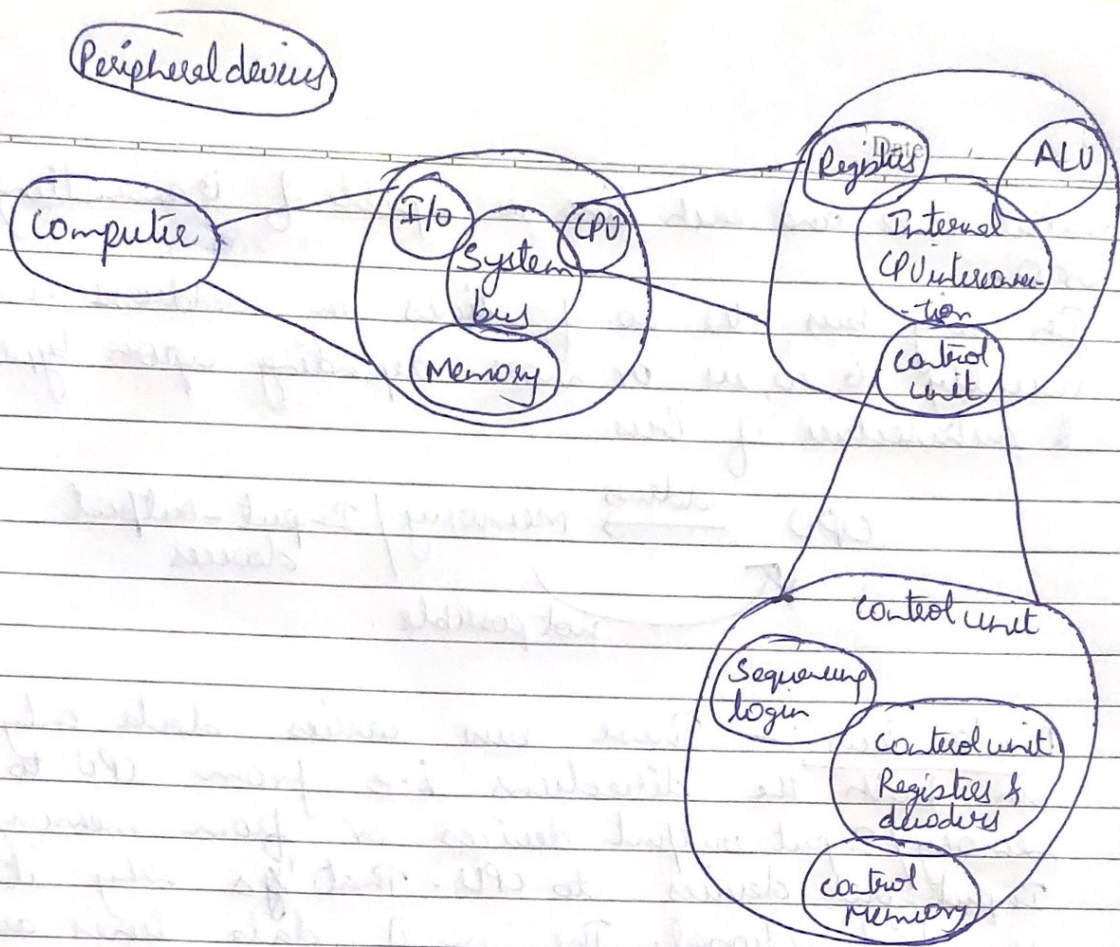

Functional units of computer:-

There are five basic functional units:-

- ① Input unit
- ② output unit
- ③ Processing unit (CPU)
- ④ Memory to store intermediate results
 - Primary
 - Secondary
- ⑤ Control unit

Bus:- Bus is a subsystem that is used to transfer data & other information b/w devices. A bus is a communication pathway and is a shared transmission medium. A bus is nothing but high speed internal connection.

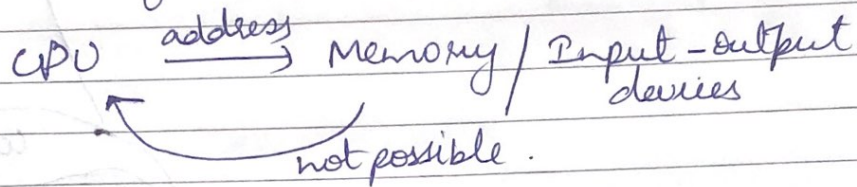

There are 3 types of buses:-

- 1) Address Bus. - carries memory addresses from processor to other components such as primary storage and input/output devices. The address bus is used to ^{enable} locate the device to locate the (MM)physical address to communicate read/write commands. The address bus is unidirectional.

Typically, a bus consist of multiple lines which are either in the form of wires or

metal lines and each line is capable of transmitting 1 or 0.

In any bus, the no. of lines in address are usually 16, 20, 24 or more depending upon type & architecture of Bus.

Data bus :- These bus carries data only in both the directions i.e. from CPU to memory/Input-output devices or from memory/Input-output devices to CPU. That's why it is bidirectional. The no. of data lines are either 8, 16, 32 or more depending on size of bus.

Control bus :- It is used by CPU to communicate with other devices within the computer. It is unidirectional/^{bidirectional} in nature. The control bus carries commands from CPU and return status signals from the devices.
